DOUGLAS-FIR TUSsock MOTH ADULT MALE SURVEY
NORTH IDAHO AND WESTERN MONTANA, 1982

by

J. E. Dewey ^{1/}, R. L. Livingston ^{2/}, and S. Kohler ^{3/}

INTRODUCTION

Douglas-fir tussock moth ^{4/} populations are monitored annually in northern Idaho and western Montana to insure early detection of changes from endemic to outbreak population levels.

Adult moth trapping in 1982 was intensified and expanded into additional areas from 1981 because of concern that with each passing year the probability of a tussock moth outbreak is more imminent. Annual increases in trap catches from 1980 through 1982 and reports during the summer of 1982 of defoliated yard and farmstead trees at various locations strongly suggest that populations are building.

This report summarizes results of the 1982 adult population monitoring.

METHODS

The pattern of trap placement and retrieval used is that described by Daterman et al. (1979), and implemented in 1981 (Dewey et al. 1982). Five sticky traps, each baited with pheromone, were used at each trapping plot. A variation from 1981 involved using Clearwater and Nezperce National Forest personnel for placement and retrieval of many of the traps in 1982. Moth identification and counting were done in the laboratory by trained people. A catch averaging 25 or more moths per trap is considered indicative of a preoutbreak population.

^{1/} Supervisory Entomologist, USDA Forest Service, Missoula, MT.

^{2/} Entomologist, Idaho Dept. of Lands, Coeur d'Alene, ID.

^{3/} Supervisor, Forest Insect and Disease Section, Division of Forestry, Montana Dept. of State Lands, Missoula, MT.

^{4/} Orgyia pseudotsugata McDunnough.

RESULTS

Survey plots were placed at 140 locations in the Northern Region in 1982. This compares to 85 plots in 1981 and 38 in 1980. The 1982 plots were located as follows: 15 in western Montana, 79 in Idaho south of Moscow and north of Riggins, and 46 plots in Idaho north of Moscow. Trap catches in 1982 were higher than 1981 catches at all three geographical locations. The greatest increases occurred in Idaho north of Moscow and in western Montana (table 1).

Table 1.--Number of trapping plots and total male moths captured from 1980-1982.

Location	1980	1981 ^{1/}	1981 ^{2/}	1982 ^{3/}	1982 ^{4/}

Idaho, N. of Moscow	19/0	19/57	18/13	37/850	7/70
Idaho, S. of Moscow	<u>11/3</u>	<u>11/63</u>	<u>24/352</u>	<u>35/506</u>	<u>44/519</u>
TOTALS	38/13	38/1,091	46/692	84/3,593	53/1,031

^{1/} Original plots sampled in 1980.

^{2/} Additional plots sampled in 1981.

^{3/} All plots sampled in 1981.

^{4/} Additional plots sampled in 1982.

In 1981, the only plots with catches exceeding an average of 25 moths/trap were five in western Montana. In 1982, 10 western Montana plots, one plot in Idaho south of Moscow, and one plot north of Moscow had more than 25 moths/trap. Several other plots had trap catches averaging between 20 and 25 moths/trap (appendix 1).

During the winter of 1981-82, three of the five plots in western Montana having 25+ moths/trap were surveyed for cocoons. Two trained observers visually surveyed host trees on the plots for 15 minutes each. No cocoons were detected. In June 1982, those same five plots plus two others were surveyed for early instar larvae using the technique described by Mason (1979). Larvae were found at four of the plots but only at such numbers to classify the population level as "low".

DISCUSSION AND RECOMMENDATIONS

All indications are that Douglas-fir tussock moth populations are increasing at a relatively rapid rate in northern Idaho and western Montana. In addition to the increase in the trap catches since 1980,

incidences of yard and farmstead trees being defoliated increased sharply in 1982. Reports have been confirmed of defoliated ornamental trees in or near Missoula, Polson, and Sommers, Montana; and Coeur d'Alene, Hayden Lake, Genesee, Craigmont, Nezperce, and Green Creek, Idaho. New epidemics reported in neighboring Washington, Oregon, and British Columbia suggest even more that our populations are building.

Because tussock moth populations can be explosive, and because widespread tree injury can result from just 1 or 2 years of defoliation, it is imperative that managers be given the maximum amount of lead time to determine their management direction. Because of this, and because data is needed to refine and validate the entire population survey system and outbreak model, it is recommended that:

1. A cocoon survey be made during the winter of 1982-83 at those plots where average trap catches exceeded 25.
2. An early instar sequential sample be taken in the spring of 1983 at all plots where moth catches approached 25 or more, and at an equal number of plots with lower moth catches.
3. A sample be made of the large larvae in the summer of 1983 to estimate population density at selected sequential sampling locations.
4. An aerial survey be conducted of all areas of high trap catches, looking for defoliation during the late summer of 1983.
5. Continue pheromone trap monitoring of all previously established plots, adding any new areas of interest.
